

IN730 Special Topic - Network Automation

Lab1 - Setting up Ansible (Local Version)

The purpose of this lab is to setup your local environment with GNS3 and Ansible and to configure them so that your GNS3 network can communicate with your Ubuntu VM that is used as your Ansible server, allowing the deployment of Ansible playbook's to your GNS3 network.

In order to do achieve this the following will be done

- Setting up an Ubuntu VM
- Setup GNS3
- GNS3 router template installation
- Configure a basic ospf network
- Connect GNS3 to your physiscal machine's Linux virtual machine
- Setup Ansible and configure ansible
- Create and deploy a simple ansible playbook

Future labs will expand upon the work that was achieved in this lab

Disclaimer

VIM is the text editor used in the following lab

The GNS3 version used at the creation of this lab was GNS3 2.2.12

Topology

Requirements

- VM Workstation
- Windows Machine
- Ubuntu 20.04

Setup

Ubuntu Setup

First thing we need to do is download a ubuntu image that we will use for our ansible server

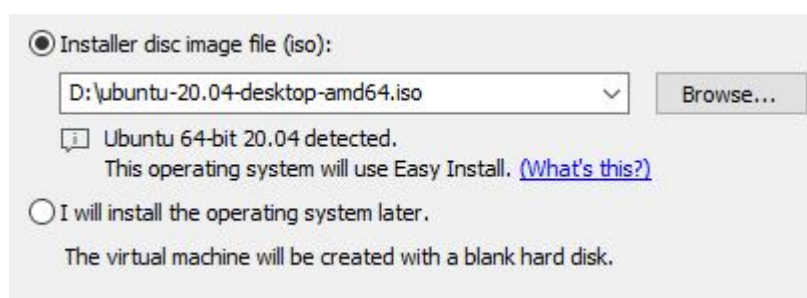

- Download Ubuntu 20.04.1 LTS image from here <https://ubuntu.com/download/desktop>

After downloading the ubuntu image we will now create a virtual machine in VM Workstation

- Launch the VM Workstation Application
- Go to File
- Select New Virtual Machine
- Select the "Typical (recommended)" option

- Select "Installer disc image file (iso):" then locate the Ubuntu iso file you downloaded earlier

- Personalize your ubuntu machine how you wish
- Leave the "Specify Disk Capacity" with the defaults

New Virtual Machine Wizard

**Specify Disk Capacity**

How large do you want this disk to be?

The virtual machine's hard disk is stored as one or more files on the host computer's physical disk. These file(s) start small and become larger as you add applications, files, and data to your virtual machine.

Maximum disk size (GB):

Recommended size for Ubuntu 64-bit: 20 GB

☐ Store virtual disk as a single file☒ Split virtual disk into multiple files

Splitting the disk makes it easier to move the virtual machine to another computer but may reduce performance with very large disks.

- Customize Hardware and change the RAM to 4GB

The virtual machine will be created with the following settings:

Location:	C:\Users\samsojl1\Documents\Virtual Machines\Ubu...
Version:	Workstation 15.x
Operating System:	Ubuntu 64-bit
Hard Disk:	20 GB, Split
Memory:	2048 MB
Network Adapter:	NAT
Other Devices:	CD/DVD, USB Controller, Printer, Sound Card

[Customize Hardware...](#)☒ Power on this virtual machine after creation

- Finish

After creating the linux VM we now need to configure some network options in VM workstation

- Click on the Edit tab and go click on the virtual network editor
- Click on the "Change Settings" option and accept the administrator prompt

⚠ Administrator privileges are required to modify the network configuration. [Change Settings](#)

- Select VMnet0 then select Bridged and bridge it to your machines physical network interface

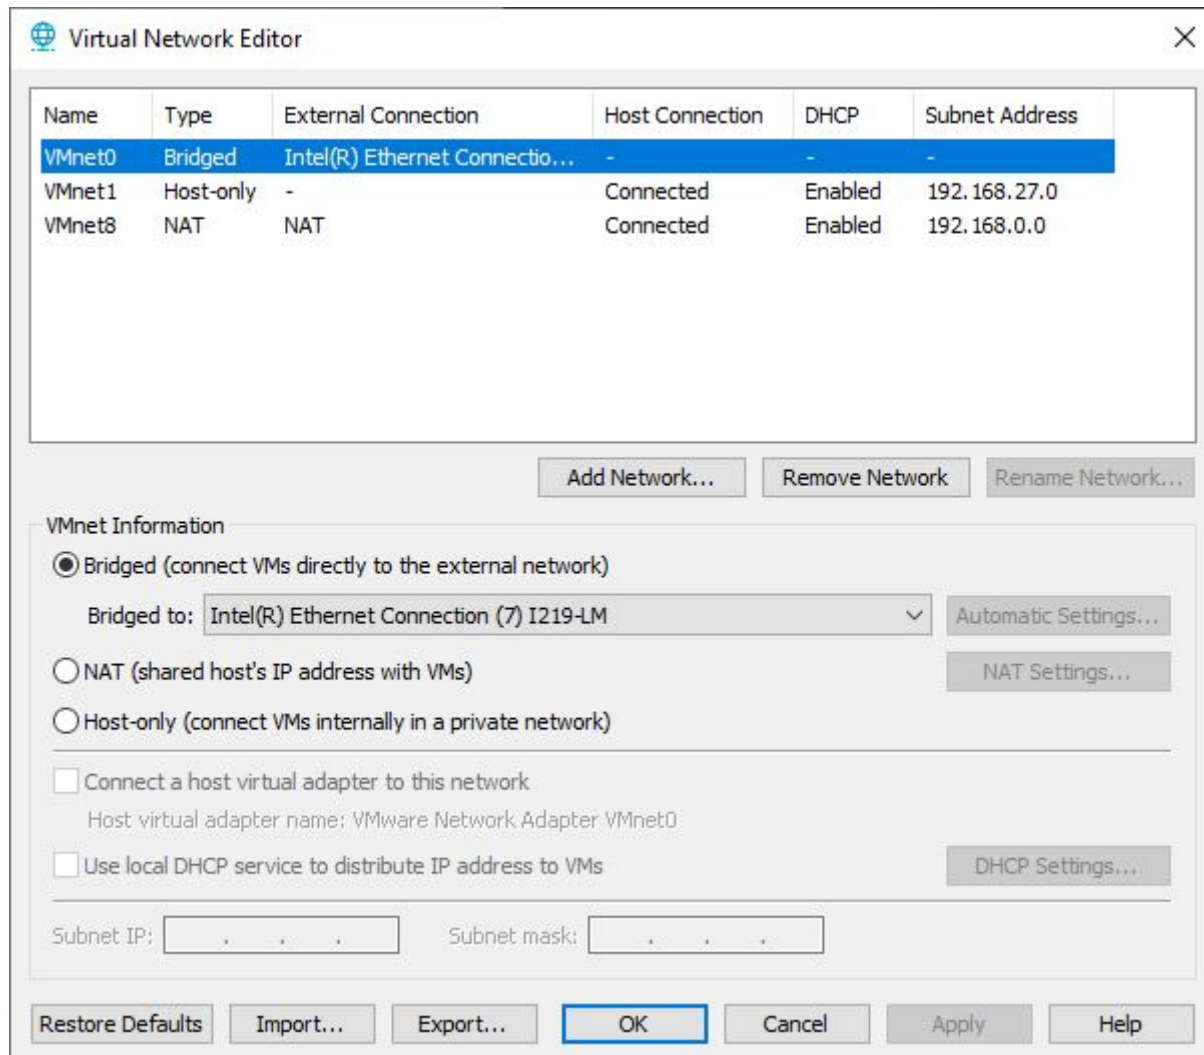

VMnet Information

☒ Bridged (connect VMs directly to the external network)Bridged to: [Automatic Settings...](#)☐ NAT (shared host's IP address with VMs)[NAT Settings...](#)☐ Host-only (connect VMs internally in a private network)

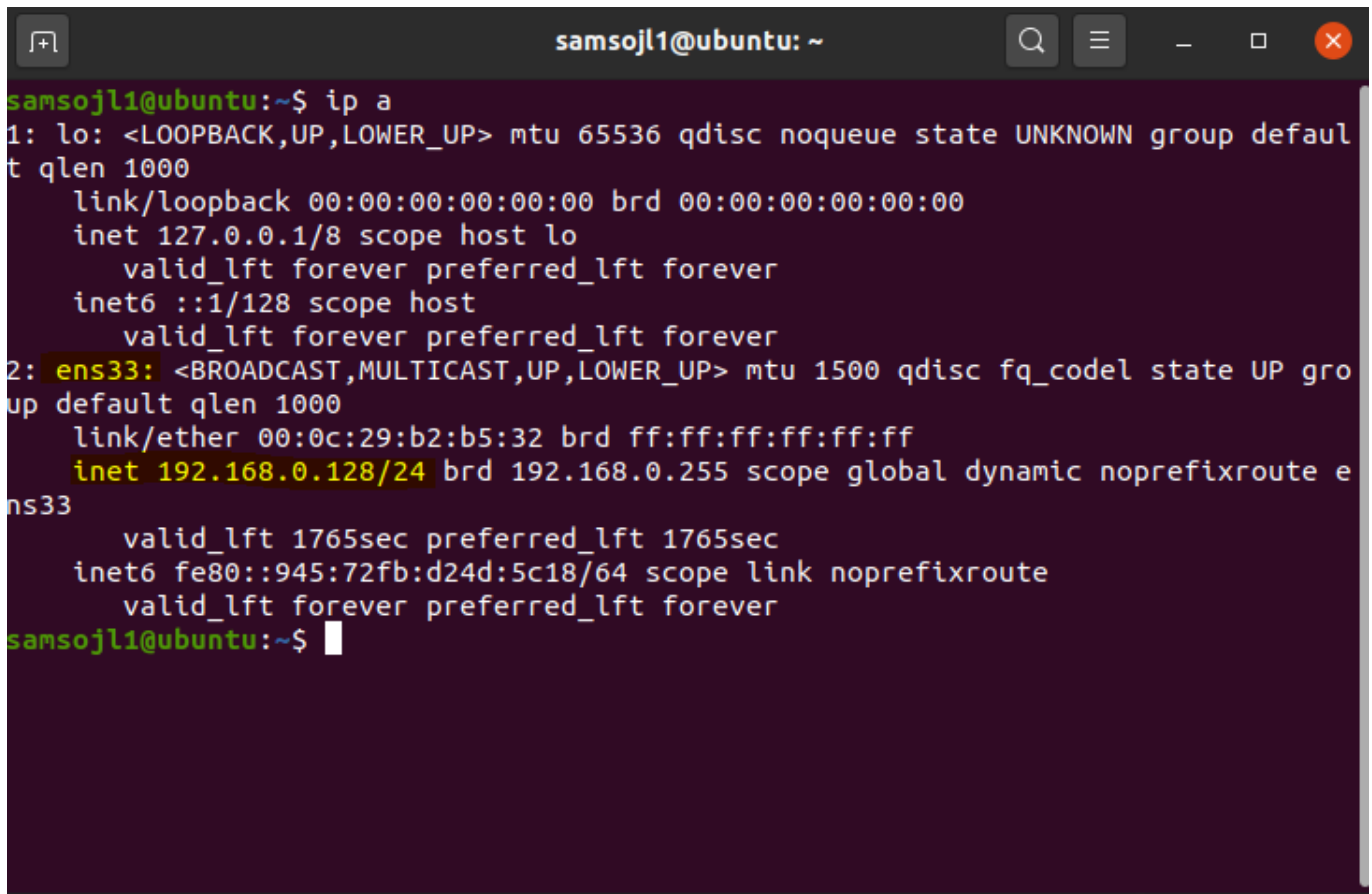

- Also select the VMnet that has the type and external connection of NAT and change its subnet ip to 192.168.0.0 with a subnet mask of 255.255.255.0

Subnet IP: Subnet mask:

In the end your Virtual Network Editor should look similar to the image below

- Connect to your Linux VM and open a terminal
- use the command "ip a" and note down the ip address on the ens33(ens number may vary but there will be only one)

A terminal window titled 'samsojl1@ubuntu: ~' with search, menu, and window control icons. The user has run the command 'ip a'. The output shows details for the loopback interface 'lo' (127.0.0.1) and the ethernet interface 'ens33' (192.168.0.128/24). The IP address 192.168.0.128/24 is highlighted in yellow in the original image.

```
samsojl1@ubuntu:~$ ip a
1: lo: <LOOPBACK,UP,LOWER_UP> mtu 65536 qdisc noqueue state UNKNOWN group default qlen 1000
    link/loopback 00:00:00:00:00:00 brd 00:00:00:00:00:00
    inet 127.0.0.1/8 scope host lo
        valid_lft forever preferred_lft forever
    inet6 ::1/128 scope host
        valid_lft forever preferred_lft forever
2: ens33: <BROADCAST,MULTICAST,UP,LOWER_UP> mtu 1500 qdisc fq_codel state UP group default qlen 1000
    link/ether 00:0c:29:b2:b5:32 brd ff:ff:ff:ff:ff:ff
    inet 192.168.0.128/24 brd 192.168.0.255 scope global dynamic noprefixroute ens33
        valid_lft 1765sec preferred_lft 1765sec
    inet6 fe80::945:72fb:d24d:5c18/64 scope link noprefixroute
        valid_lft forever preferred_lft forever
samsojl1@ubuntu:~$
```

This ip will be used later when we configure GNS3

GNS3 Setup

In order to download GNS3 you need to sign up to their website

- Sign up to GNS3 <https://www.gns3.com/>
- Download the windows version of GNS3 <https://www.gns3.com/software/download>

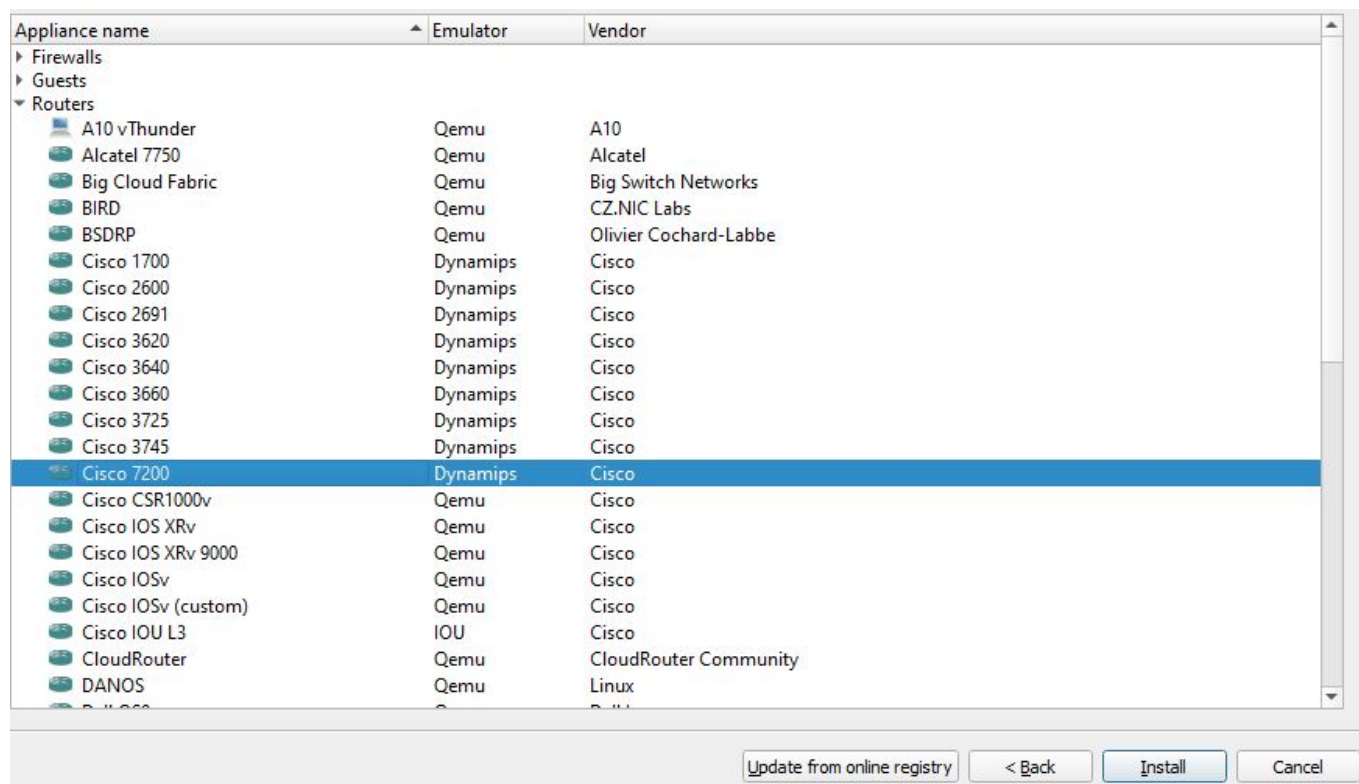

Router Template Configuration

We need to download and configure a router template that we will use within GNS3, GNS3 by default does not come with any routers that you can use.

- Download the image for the cisco 7200 router here <https://github.com/samsojl1/Otago-Polytechnic/raw/master/Special-Topic/c7200/c7200-adviservicesk9-mz.122-33.SRC2.extracted.bin>

In order to create a template using the image we just downloaded we need to do the following

- In GNS3 go to File > New Template
- Install an appliance from the GNS3 server
- Then click the dropdown for the routers section and select Cisco 7200 then click install

- Install the appliance on your local computer
- Select Create a new version
- Name it "C7200" and select ok

- You should now see your router but with its files missing

- select your version from the list and click import, locate and select the c7200-advipservicesk9-mz.122-33.SRC2.extracted.bin image you downloaded
- Next
- Accept the install

- Finish

If you click on the router icon on the left hand side

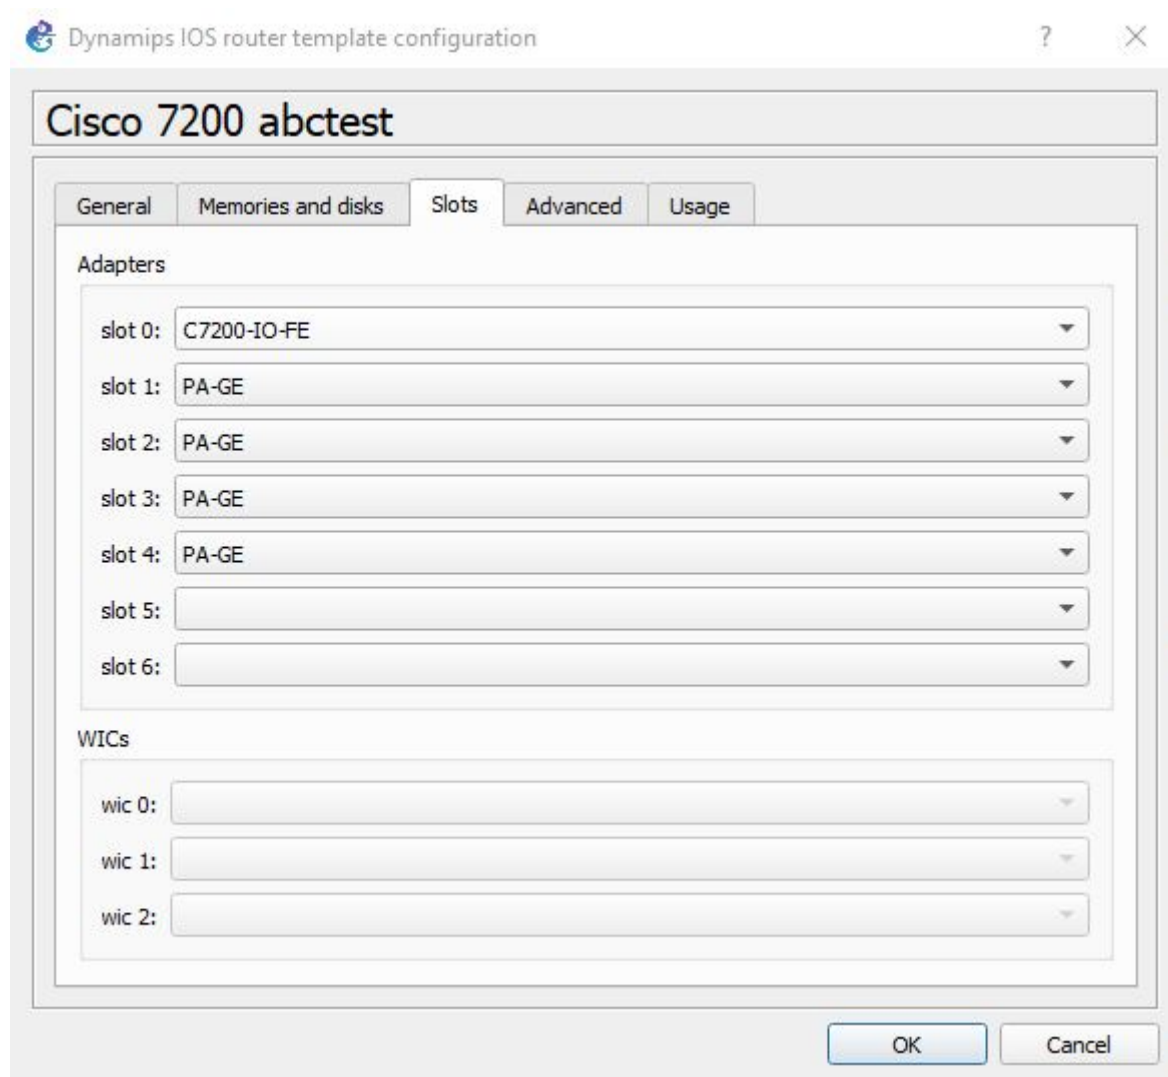

You should now see your router template you installed

We now need to make a few tweaks to our newly created template

- Right click your router template and select the configure template option

- Go to the "Slots" tab and add "PA-GE" to Adapters slots 1 through 4 this will add gigabyte interfaces to your routers when you create them

Configure A Basic Network

Let's create a simple network in GNS3

- Create a new blank project
- Add 2 routers to the project
- Cable these 2 routers together according to the topology above

On R1

```

end
conf t
int g1/0
ip address 192.168.1.1 255.255.255.252
no shut

```

On R2

```

end
conf t
int g1/0
ip address 192.168.1.2 255.255.255.252
no shut

```

Verify that R1 can ping R2 and R2 can ping R1

Now we will add a cloud to our GNS3 project

The cloud allows the routers inside your GNS3 project to communicate with outside devices

Lets add a cloud to connect our virtual routers to our physical network

- From the browse end devices tab

- Add the cloud to your project

After adding the cloud we now need to configure it

- Click on the cloud and go to "Ethernet Interfaces" tab
- Tick the "Show special Ethernet interfaces" option
- Click the Add all button

By selecting the add all option this will add all the interfaces from your physical machine to the cloud allowing you to connect your virtual router to it

- Cable R1 to the Cloud according to the topology

On the interface you connected your R1 to the cloud you need to configure it with an ip in the same range as the physical interface, the ens33 ip you recorded earlier

On R1

```
end
conf t
int g2/0
ip address 192.168.0.1 255.255.255.0
no shut
```

Configure OSPF and a static default route then redistribute that route into ospf

On R1

```
end
conf t
ip route 0.0.0.0 0.0.0.0 192.168.0.128
router ospf 1
router-id 1.1.1.1
network 192.168.0.0 0.0.0.255 area 0
network 192.168.1.0 0.0.0.3 area 0
default-information originate
```

On R2

```
end
conf t
router ospf 1
router-id 2.2.2.2
network 192.168.1.0 0.0.0.3 area 0
```

Because ansible is agentless and uses SSH to deploy playbooks, you will need to configure and enable SSH onto your GNS3 Routers, a basic configuration has been provided

```
end
conf t
ip domain-name ansible.com
crypto key generate rsa
1024
ip ssh version 2
username admin privilege 15 password 0 admin
line vty 0 4
login local
transport input ssh
exit
```

Linux Routing

On your linux vm you will need to configure a route so that traffic knows where to go to to get to your GNS3 routers

In your Linux terminal use the following command

```
sudo ip route add 192.168.1.0/30 via 192.168.0.128 dev ens33
```

Do note that routes configured this way aren't persistent and will need to be re entered, you can configure them to be persistent but for what we are trying to do that isn't required

Ansible Setup

Now that everything has been configured so that we can use ansible it is time to setup ansible

On your Linux VM open a terminal and use the command

```
sudo apt-get install ansible -y
```

This will download and install ansible onto the Linux machine

After we have installed ansible we now need to make some configurations to it

Go to the ansible directory

```
cd /etc/ansible/
```

Inside this directory you will find the ansible.cfg and hosts file, this is also where you will create your ansible playbooks to begin with

We will disable host_key_checking in our ansible.cfg file so that we don't need to SSH onto our GNS3 routers first before we can deploy playbooks, while this helps to save time in a lab environment it is also a security risk

```
sudo vim /etc/ansible/ansible.cfg
```

Go to line 62 and uncomment the following

```
#host_key_checking = False
```

Then save the file

Inside the hosts file you can define your network devices and assign them to groups an example of this provided inside the file by ansible

The following is to be added to our hosts file

```
[routers]
R2 ansible_host=192.168.1.2 ansible_network_os=ios ansible_ssh_user=admin
ansible_ssh_pass=admin
R1 ansible_host=192.168.0.1 ansible_network_os=ios ansible_ssh_user=admin
ansible_ssh_pass=admin
```

- The [routers] defines the name of the group this can be called whatever you wish
- R2 and R1 are the names of the hosts
- ansible_host=X.X.X.X is the ip of the host
- ansible_network_os=ios defines the network platform that the host is using
- ansible_ssh_user=admin the user account that ansible uses to connect with in this example its admin because that is what we created earlier when we setup the router configuration in gns3
- ansible_ssh_pass=admin the password of the user account that ansible is using to connect with

Now that we have everything setup we can finally use ansible

Let's create a simple playbook to test if everything is working correctly

```
sudo vim /etc/ansible/test.yaml
```

And insert the following

```
---
- name: ping
  hosts: routers
  connection: local
  gather_facts: false
  tasks:
    - ping:
```

In order to run your ansible playbook that you have now created you need to be located in the directory that the playbook was made

```
cd /etc/ansible
ansible-playbook test.yaml
```

After running that command the following output should occur

```
samsoj11@ubuntu:/etc/ansible$ ansible-playbook test.yaml
PLAY [testbook] *****
TASK [ping] *****
ok: [R2]
ok: [R1]
PLAY RECAP *****
R1                : ok=1    changed=0    unreachable=0    failed=0    skipped=0    rescued=0    ignored=0
R2                : ok=1    changed=0    unreachable=0    failed=0    skipped=0    rescued=0    ignored=0
```

Congratulations you have now successfully deployed your first ansible playbook

In future labs we will cover more uses for ansible in both a local and cloud environment

Please save your work or make a script to recreate it quickly along as future labs will be built off this

Further reading:

ansible module list can be found here

- https://docs.ansible.com/ansible/latest/user_guide/playbooks.html

Troubleshooting

If at some point your pings / connection stops working between your linux vm and your GNS3 routers, delete the cable connecting R1 and the cloud together then cable them back together
